DataVariablesAndOperations

July 16, 2021

1 Data, Variables and Operations

1.1 Topics

- data and values
- C++ fundamental data types
- digital units and number systems
- variables and data assignment
- keywords and operators
- order of operations
- operators for numbers and strings
- constants
- type casting

1.2 Data and values

- data and values are the fundamentals to any computer language and program
- a value is one of the fundamental things like a letter or a number that a program manipulates
- almost all computer programs use and manipulate some data values

1.3 Literal values and representations

- at a high level, we deal with two types of data values: Numbers and Texts
- numbers can be further divided into two types:
 - Whole number literal values: 109, -234, etc.
 - Floating point literal values: 123.456, -0.3555, etc.
- text is a collection of 1 or more characters (symbols, digits or alpahabets)
 - single character is represent using single quote (')
 - * char literal values: 'A', 'a', '%', '1', etc.
 - 2 or more characters are called string
 - * represented using double quotes (")
 - * string literal values: "CO", "John Doe", "1100", etc.
- programming languages need to represent and use these data correctly

1.4 C++ fundamental types

- there are many fundamental types based on the size of the data program needs to store
 - most fundamental types are numeric types

- see here for all the supported types: https://en.cppreference.com/w/cpp/language/types
- the most common types we use are:

Type	Description	Storage size	Value range
void	an empty set of values; no type	system dependent: 4 or 8 bytes	NA
bool	true or false	1 byte or 8 bits	true or false 1 or 0
char	one ASCII character	1 byte or 8 bits	-2^7 to $2^7 - 1$
unsigned char	one ASCII character	1 byte or 8 bits	0 to $2^8 - 1$
int	+/-ve integers	4 bytes	-2^{31} to $2^{31}-1$
unsigned int	only positive integers	4 bytes or 32 bits	0 to $2^{32} - 1$
long	+ve and -ve big integers	8 bytes or 64 bits	-2^{63} to $2^{63}-1$
unsigned long	positive big integers	8 bytes or 64 bits	0 to $2^{64} - 1$
float	single precision floating points	32 bits	7 decimal points
double	double precision floating points	64 bits	15 decimal points

- in C++, there's no fundadamental type available to work with string data
- two common ways to store string data:
 - use C-string or array of characters
 - use basic_string defined in <string> library
 - * more on basic_string: https://en.cppreference.com/w/cpp/string/basic_string
 - * must include <string> library and std namespace
- we'll dive into string more in depth in **Strings** chapter

1.4.1 sizeof operator

- one may want to know the size of memory allocated for the fundamental types
 - some of these types are system dependent (e.g., long is 32 bit in x86 and 64 bit in x64)
- sizeof(type) operator gives size of fundamental types in bytes
- let's check the size of some fundamental types on my 64-bit MacBook Pro laptop
- [1]: sizeof(bool)
 [1]: 1
 [2]: sizeof(char)
 [2]: 1
 [3]: sizeof(int)
 [3]: 4
 [4]: sizeof(long)
 [4]: 8

- [5]: 4
- [6]: sizeof(double)
- [6]: 8

1.5 Units of digital data

- digital computers use binary number system consisting of two digits (0 and 1)
- every data and code is represented using binary values
 - hence the name binary or byte code for executable programs
 - letter A is encoded as 1000001 (7 binary digits)
- humans use decimal number system with 10 digits (0 to 9)
 - we have ways to represent texts using alphabets for English language e.g.: Hello Bond 707!
 - texts must be encoded into numbers, if we lived in the world that only understood numbers
- the following table shows the various units of digital data

Unit	Equivalent
1 bit (b)	0 or 1
1 byte (B)	8 bits (b)
1 kilobyte (KB)	$1,024~{\rm B}$
1 megabyte (MB)	$1,024~\mathrm{KB}$
1 gigabtye (GB)	$1,024~\mathrm{MB}$
1 terabyte (TB)	$1,024~\mathrm{GB}$
1 petabyte (PB)	1,024 TB

1.6 Number systems

- there are several number systems based on the base digits
 - base is number of unique digits number system uses to represent numbers
- binary (base 2), octal (base 8), decimal (base 10), hexadecimal (base 16), etc.

1.6.1 Decimal number system

- also called Hindu-Arabic number system
- most commonly used number system that uses base 10
 - has 10 digits or numerals to represent numbers: 0..9
 - e.g., 1, 79, 1024, 12345, etc.
- numerals representing numbers have different place values depending on position:
 - ones (10^0) , tens (10^1) , hundreds (10^2) , thousands (10^3) , ten thousands (10^4) , etc.
 - $\text{ e.g.}, 543.21 = (5 \times 10^2) + (4 \times 10^1) + (3 \times 10^0) + (2 \times 10^{-1}) + (1 \times 10^{-2})$

1.7 Number system conversion

- since computers understand only binary, everything (data, code) must be converted into binary
- all characters (alphabets and symbols) are given decimal codes for electronic communication
 - these codes are called ASCII (American Standard Code for Information Interchange)
 - $-A \to 65; Z \to 90; a \to 97; z \to 122, * \to 42, \text{ etc.}$
 - see ASCII chart: https://en.cppreference.com/w/c/language/ascii

1.7.1 Converting decide to binary number

- algorithm steps:
 - 1. repeteadly divide the decimal number by base 2 until the quotient becomes 0
 - note remainder for each division
 - 2. collect all the remainders in reverse order
 - the first remainder is the last (least significant) digit in binary
- example 1: what is decimal $(10)_{10}$ in binary $(?)_2$?
 - step 1:

```
\frac{10}{2} = quotient: 5, remainder: 0 \frac{5}{2} = quotient: 2, remainder: 1 \frac{2}{2} = quotient: 1, remainder: 0 \frac{1}{2} = quotient: 0, remainder: 1
```

- step 2:
 - * collect remainders from bottom up: 1010
- $\text{ so, } (10)_{10} = (1010)_2$
- example 2: what is decimal $(13)_{10}$ in $(?)_2$?
 - step 1

```
\frac{13}{2} = quotient: 6, remainder: 1\frac{6}{2} = quotient 3, remainder: 0\frac{3}{2} = quotient: 1, remainder: 1\frac{1}{2} = quotient: 0, remainder: 1
```

- step 2:
 - * collect remainders from bottom up: 1101
- $so, (13)_{10} = (1101)_2$

1.7.2 Converting binary to decimal number

- once the computer does the computation in binary, it needs to convert the results back to decimal number system for humans to understand
- algorithm steps:
 - 1. multiply each binary digit by its place value in binary
 - 2. sum all the products
- example 1: what is binary $(1010)_2$ in decimal $(?)_{10}$?
 - step 1:

$$* 0 \times 2^0 = 0$$

$$* 1 \times 2^1 = 2$$

$$* 0 \times 2^2 = 0$$

$$* 1 \times 2^3 = 8$$

- step 2:

$$* 0 + 2 + 0 + 8 = 10$$

$$-$$
 so, $(1010)_2 = (10)_{10}$

- example 2: what is binary $(1101)_2$ in decimal $(?)_{10}$?
 - step 1:

```
 * 1 \times 2^{0} = 1 
 * 0 \times 2^{1} = 0 
 * 1 \times 2^{2} = 4 
 * 1 \times 2^{3} = 8 
 - \text{ step } 2: 
 * 1 + 0 + 4 + 8 = 13 
 - \text{ so, } (1101)_{2} = (13)_{10}
```

- we got the same decimal vales we started from in previous examples
- food for thought: think how you'd go about writing a program to convert any positive decimal number into binary and vice versa!

1.8 Negative (signed) integers - Two's complement

- most common method of storing negative numbers on computers is a mathematical operation called Two's complement
- Two's complement of an N-bit number is defined as its complement with respect to 2^N
 - the sum of a number and its two's complement is 2^N
- e.g.: for the 3-bit binary number 010₂, the two's complement is 110₂
 - because $010_2 + 110_2 = 1000_2 = 2_{10}^3$
- Two's complement of N-bit number can be found by flipping each bit and adding one to it
- e.g. find two's complement of 010
 - Algorithm steps:
 - 1. flipped each bit; 0 is flipped to 1 and 1 is flipped to 0 010 \rightarrow 101
 - 2. add 1 to the flipped binary

101 +1 -----110

1.8.1 Example: What is -3 decimal in 8-bit binary representation?

- convert 3_10 to an 8-bit binary
 - $-\ 3_{10} \rightarrow 00000011_2$
- 1. find Two's complement of 8-bit binary
 - $00000011_2 \rightarrow 111111100_2 + 1 = 111111101_2$
- 2. Sanity check:
 - $00000011_2 + 111111101_2 = 1000000000_2 = 2_{10}^8$
- So, $-3_{10} = 111111101_2$ in an 8-bit representation

1.9 Exercise

- 1. Convert decimal integer 7 into binary with 16 bits.
- 2. Convert -7 decimal integer into binary with 16 bits.

1.10 Variables

• programs must load data values into memory to manipulate them

- data may be large and used many times during the program
 - typing the data values literally all the time is not efficient and fun
 - most importantly error prone due to typos
 - you may not even know that values may be if they're read from standard input, files, etc.
- variables are named memory location where data can be stashed for easy access and manipulation
- one can declared and use as many variables as necessary
- C++ is statically and strongly typed programming language
 - variables are tied to their specific data types that must be explictly declared when declaring variables

1.10.1 Variable declaration

- statements that create variables/identifiers to store some data values
- as the name says, value of variables can vary/change over time
- syntax:

type varName; type varNam1, varName2, ...; //declare several variables all of the same type

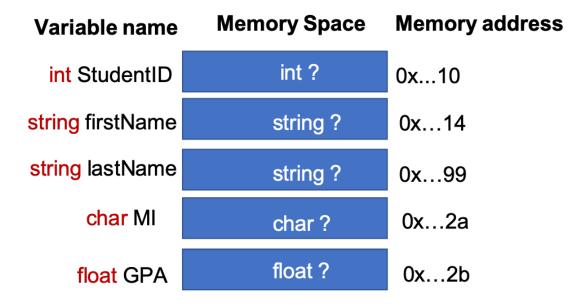

Fig. C++ Variables and Memory

1.10.2 Rules for creating variables

- variable names are case sensitive
- must declare variables before they can be used
- can't define variable with the same name more than once
- can't use keywords as variable names

- data stored must match the type of variable
- variable names can't contain symbols (white spaces, #, &, etc.) except for _ and \$ (under-score and dollar)
- variable names can contain digits but can't start with a digit
- variable names can start with only alphabets (lower or upper) and _ symbol

1.10.3 Best practices

- use descriptive and meaningful but concise name
 - one should know quickly what data you're storing
- use lowercase; camelCase or (_ underscore) to combine multiple words

1.10.4 C++ keywords

- keywords are reserved names and words that have specific purpose in C++
 - they can only be used what they're intended for
- e.g., char, int, unsigned, signed, float, double, bool, if, for, while, return, struct, class, operator, try, etc.
- all C++ keywords are listed here: https://en.cppreference.com/w/cpp/keyword

```
[7]: // examples of variable declaration
bool done;
char middleInitial;
char middleinitial; // hard to read all lowercase name
int temperature;
unsigned int age;
long richest_persons_networth;
float interestRate;
float length;
float width;
double space_shuttle_velocity;
```

```
[8]: // TODO: // Declare 10 variables of atleast 5 different types
```

1.10.5 String variables

- declare variables that store string data
 - 1 or more string of characters
- an easy way to use string is by using C++ advanced type defined in <string> header file
- must include <string> header file or library to use string type
- must also use **std** namespace
- strings are represented using a pair of double quotes ("string")
- more on string type is covered in **Strings** chapter
- the following are some examples of string variables

```
[9]: // string variables #include <string>
```

```
using namespace std;

string fullName;
string firstName;
string address1;
string country;
string state_name;
std::string state_code; // :: name resolution operator
```

```
[10]: // TODO: // Declare 5 string variables
```

1.11 Assignment operator (=)

- once variables are declared, data can be stored using assignment operator, \$ = \$
- assignment statements have the following syntax:

varName = value;

• since C++ is a strongly typed language, the type of value must match the type of variable – strongly typed languages enforces type safety and matching during the compile time

```
[11]: // assignment examples
    done = false;
    middleInitial = 'J'; // character is represent using single quote
    middleinitial = 'Q';
    temperature = 73;
    age = 45;
    richest_persons_networth = 120000000000; // 120 billion
    interestRate = 4.5;
    length = 10.5;
    width = 99.99f; // number can end with f to represent as float
    space_shuttle_velocity = 950.1234567891234567; // 16 decimal points
```

[11]: 950.123

```
[12]: // string assignment examples
fullName = "John Doe";
firstName = "John";
address1 = "1100 North Avenue"; // number as string
country = "USA";
state_name = "Colorado";
state_code = "CO";
```

```
[13]: // TODO: assign different values to variables defined above
```

1.11.1 Variable declaration and initialization

- variables can be declared with initial value at the time of construction
- if you know what value a variable should start with; this saves you typing
- often times its the best practice to initialize variable with default value
- several ways to initialize variables: https://en.cppreference.com/w/cpp/language/initialization
- two common ways:
 - 1. Copy initialization (using = operator)
 - 2. Value initialization (using { } curley braces)
 - also called uniform initialization
 - useful in initializing advanced types such as arrays, objects, etc.

```
[14]: // Copy initialization
float price = 2.99f;
char MI = 'B'; //middle initial
string school_name = "Grand Junction High";
```

```
[15]: // Value/uniform initialization
    char some_letter{'U'};
    int some_length{100};
    float some_float{200.99};
    string some_string = {"Hello World!"}; // can also combine the two!
```

1.11.2 Variable's value can be changed

- variable's value can vary through out the program
 - hence the name variable
- however, type of the value must be same as the type of the variable declared
- C++ is a strongly and statically typed programming language!

```
[16]: price = 3.99;
    price = 1.99;
    MI = 'Q';
    school_name = "Fruita Monument High";
    some_string = "Goodbye, World!";
```

```
[17]: price = "4.99"; // is this valid?
input_line_34:2:10: error: assigning to 'float' from
```

Interpreter Error:

1.11.3 auto type

• if variable is declared and initialized in one statement, you can use **auto** keyword to let compiler determine type of variable based on the value it's initialized with

```
[18]: auto var1 = 10; // integer
      auto var2 = 19.99f; // float
      auto var3 = 99.245; // double
      auto var4 = '@'; // char
[19]: // char * (pointer) type and not string type
      auto full_name = "John Doe";
[20]: // can automatically declare string type
      #include <string>
      using namespace std;
      auto full_name1 = string("Jake Smith"); // string type!
[21]: // use typeid function to find the name of the types
      // typeid is defined in typeinfo library
      #include <typeinfo>
[22]: typeid(full_name1).name()
[22]: "NSt3__112basic_stringIcNS_11char_traitsIcEENS_9allocatorIcEEEE"
[23]: // should print "i" -> short for integer
      // Note: may also print invalid memory address in Jupyter notebook!
      typeid(var1).name()
[23]: "i"
```

1.11.4 Visualize variables and memory with pythontutor.com

1.12 Operators

- special symbols used to represent simple computations
 - like addition, multiplication, modulo, etc.
- C++ has operators for numbers, characters, and strings
- operators and precedence rule: https://en.cppreference.com/w/cpp/language/operator precedence
- arithmetic operators: https://en.cppreference.com/w/cpp/language/operator arithmetic

1.12.1 Unary operators

- takes one operand
- operands are values that operators work on
- there are two unary operators for numeric operands

Operator	Symbol	Syntax	Operation
positive	+	+100	positive 100 (default)
negative	-	-23.45	negative 23.45

1.12.2 Binary operators

- binary operators take two operands (left operator right)
- the following table shows the binary operators for numeric operands

Operator	Symbol	Name	Syntax	Operation
add	+	plus	x + y	add the value of y with the value of x
subtract	-	hyphen	x - y	subtract y from x
multiply	*	asterick	x * y	product of x and y
divide	/	slash	x / y	divide x by y (int division if x and y are both ints)
modulo	%	percent	x % y	remainder when x is divided by y

1.12.3 Adding numbers

float total = n1+n2;

• + symbol is used to add literal values or variables

```
[24]: // adding literal integer values
      +1 + (-1)
[24]: 0
[25]: // adding literal floating points
      99.9 + 0.1
[25]: 100
[26]: // adding int variables
      int num1, num2, sum;
[27]: num1 = 10;
      num2 = 5;
      sum = num1 + num2;
[28]: // let's see the value of sum
      sum
[28]: 15
[29]: // adding float variables
      float n1 = 3.5;
      float n2 = 2.5;
```

```
[30]: // see total values
      total
[30]: 6f
     1.12.4 Subtracting numbers
        • - symbol is used to subtract literal numbers or variables
[31]: // subtracting literal integers
      10-1
[31]: 9
[32]: // subtracting literal floating points
      99.99 - 10.99
[32]: 89
[33]: // subtracting variables
      num1-num2
[33]: 5
     1.12.5 Multiplying numbers
        • * asterick symbol is used to multiply literal numbers and variables
[34]: // multiplying literal integers
      2*3
[34]: 6
[35]: // multiplying literatl floats
      2.5 * 2.0
[35]: 5
```

1.12.6 Dividing numbers

[36]: // multiplying numeric variables

n1*n2

[36]: 8.75f

• / symbol is used to divide literal numbers or variables

```
[37]: // dividing literal integers
      10/2
[37]: 5
[38]: 9/2 // integer division; remainder is discarded
[38]: 4
[39]: // dividing literal floats
      // if one of the operands is floating point number, C++ performs float division
      9.0/2
[39]: 4.5
[40]: // dividing numeric variables
      n1/n2
[40]: 1.4f
     1.12.7 Capturing remainder from a division
        \bullet use modulo or remainder ( \% ) operator to find the remainder of literal values or variables
        • only works on positive integers
[41]: // modulo or remainder operator
      5%2 // testing for odd number
[41]: 1
[42]: 4%2 // testing for even number
[42]: 0
[43]: // can't divide 10 by 11
      10%11
[43]: 10
[44]: // expressions with variables and literals
      // declare some variables
      int hour, minute;
[45]: // assign some values
      hour = 11;
      minute = 59;
```

[46]: // Number of minutes since midnight hour * 60 + minute

[46]: 719

[47]: // Fraction of the hour that has passed minute/60

[47]: 0

1.12.8 Exercise

• How many hours and minutes are in 121 minutes?

1.12.9 Bitwise operators

- https://www.learncpp.com/cpp-tutorial/38-bitwise-operators/
- bitwise operators work on binary numbers (bits)
 - integers are implicitly converted into binary and then bitwise operations are applied
- bitwise operations are used in lower-level programming such as device drivers, low-level graphics, communications protocol packet assembly, encoding and decoding data, encryption technologies, etc.
- a lot of integer arithmetic computations can be carried our much more efficiently using bitwise operations

Operator	Symbol	Symbol Name	Syntax	Operation
bitwise left shift	«	left angular bracket	x « y	all bits in x shifted left y bits; multiplication by 2^y
bitwise right shift	»	right angular bracket	x » y	all bits in x shifted right y bits; division by 2^y
bitwise NOT	~	tilde	~X	all bits in x flipped
bitwise AND	&	ampersand	x & y	each bit in x AND each bit in y
bitwise OR		pipe	x y	each bit in x OR each bit in y

Operator	Symbol	Symbol Name	Syntax	Operation
bitwise XOR	^	caret	x ^ y	each bit in x XOR each bit in y

1.12.10 Table for bitwise operations

x	у	х & у
1	1	1
1	0	0
0	1	0
0	0	0

& - bitwise AND

x	у	$x \mid y$
1	1	1
1	0	1
0	1	1
0	0	0

| - bitwise OR

$$\begin{array}{ccc} x & \sim x \\ \hline 1 & 0 \\ 0 & 1 \\ \hline \end{array}$$

\sim - bitwise NOT

x	у	x ^ y
1	1	0
1	0	1
0	1	1
0	0	0

$\hat{\ }$ - bitwise XOR

bitwise left shift examples

```
[1]: // convert 1 decimal to binary and shift left by 4 bits 1 << 4 // same as 1*2*2*2; result is in decimal
```

[1]: 16

Explanation

- Note: in the given example, binary uses 32-bit to represent decidal

```
[1]: 3 << 4 // same as 3*2*2*2*2 or 3*2<sup>4</sup>
```

[1]: 48

Explanation

- $\bullet \ \ 3 << 4 = 000000000000000000000000110000_2 = 2^5 + 2^4 = 32 + 16 = 48_{10}$

Bitwise right shit examples

```
[50]: 1024 >> 10 // same as 1024/2/2/2/2/2/2/2/2
```

[50]: 1

Explanation

Bitwise NOT examples

```
[52]: ~0 // result shown is in decimal!
```

[52]: -1

```
[51]: \[ \tau' \] Note: 1 in binary using 32-bit width (31 0s and 1) 00000....1 \[ // result shown is in decimal \]
```

[51]: -2

Explanation

- $\bullet\,$ Note: -ve numbers are stored in Two's complement
 - 2's complement is calculated by flipping each bit and adding 1 to the binary of positive integer

Bitwise AND examples [53]: 1 & 1 [53]: 1 [54]: 1 & 0 [54]: 0 [55]: 0 & 1 [55]: 0 [56]: 0 & 0 [56]: 0 Bitwise OR examples [57]: 1 | 1 [57]: 1 [58]: 1 | 0 [58]: 1 [59]: 0 | 1 [59]: 1 [60]: 0 | 0 [60]: 0 Bitwise XOR examples [61]: 1 ^ 1 [61]: 0 [62]: 1 ^ 0

```
[62]: 1
[63]: 0 ^ 1
[63]: 1
[64]: 0 ^ 0
[64]: 0
     1.13 Order of operations
        • expressions may have more than one operators
        • the order of evaluation depends on the rules of precedence
     1.13.1 PEMDAS
        • acronym for order of operations from highest to lowest
             1. P : Parenthesis
             -\mathbf{E}: Exponentiation
             -\mathbf{M}: Multiplication
             - D : Division
             - A : Addition
             -\mathbf{S}: Subtraction
        • when in doubt, use parenthesis!
[18]: // computation is similar to what we know from Elementary Math
      2+3*4/2-2
[18]: 6
 [2]: // same as
      (2+((3*4)/2))-2
 [2]: 6
[29]: (2+3)*4/(2-1) // Note: must use * to multiply after ( )
[29]: 20
     (2+3)4/(2-1) // error
     input_line_13:2:7: error: expected ';' after
     expression
       (2+3)4/(2-1)
```

;

Interpreter Error:

1.14 Operators for characters

- mathematical operators also work on characters
- characters' ASCII values are used in computations
- C++, when safe, converts from one type to another; called type **coercion**
 - characters are converted into their corresponding integer ASCII values
 - coercion is safe when data is not lost, e.g. converting int to float

```
[30]: 'a'+1 // a -> 97

[30]: 98

[31]: 'A'-1 // A -> 65

[31]: 64

[24]: 'A'*10

[24]: 650

[33]: 'A'/10

[33]: 6

[34]: 'A'+'A'

[34]: 130
```

1.15 Operators for strings

- certain operators are defined or overloaded for string types
 - more on user defined advanced types and operator overloading later
- +: concatenates or joins two strings giving a new longer string

```
[36]: // variables can be declared and intitialized at the same time
    #include <iostream>
    #include <string>
    using namespace std;

string fName = "John";
```

```
string lName = "Smith";
      string space = " ";
      string fullName = fName + space + lName;
[38]: fullName
[38]: "John Smith"
     1.16 Constants
        • constants are named values that remain unchanged through out the program
        • useful for declaring values that are fixed
             - e.g. value of \pi, earth's gravity, unit conversions, etc.
        • two ways to define constants in C++
            1. use const keyword infront of an identifier
                 - syntax:
               const type identifier = value;
            2. use #define preprocessor directive
                 - syntax:
               #define identifier value
                 - after an identifier has been defined with a value, preprocessor replaces each occu-
                   rances of PI with value
[40]: const double pi = 22/7.0; // evaluate 22/7.0 and use it as the const value for
       \hookrightarrow pi
      const float earth_gravity = 9.8; // m/s^2 unit
[41]: // let's see the value of constant pi
      рi
[41]: 3.1428571
[42]: // try to assign different value to the constant pi
      pi = 3.141592653589793238;
     input_line_83:3:4: error: cannot assign to variable
     'pi' with const-qualified type 'const double'
     pi = 3.141592653589793238;
     input_line_80:2:15: note: variable 'pi' declared const
      const double pi = 22/7.0; // evaluate 22/7.0 and use it as the const value for
```

Interpreter Error:

```
[43]: // let's use constants
    double radius = 10.5;
    double area_of_circle = pi*radius*radius;

[44]: // value of area of circle
    area_of_circle

[44]: 346.50000

[45]: // preprocessor directive to declare named constant
    #define PI 3.141592653589793238

[46]: PI*radius*radius

[46]: 346.36059
```

1.16.1 floating point operation accuracy

- floating point calculations may not be always 100% accurate
- you have to choose the accuracy upto certain decimal points to accept the results as correct
- google area of circle
 - use same radius 10.5 and compare the results provided above

1.17 Type casting

- data values need to be converted from one type to another to get correct results
- explictly converting one type into another is called **type casting**
- implict conversion is called **coercion**
- not all values can be converted from one type to another!

1.17.1 Converting numeric values to string type

- use to_string(value) function to convert value to string
- must include <string> header and std namespace

```
[6]: #include <string>
using namespace std;

string str_val = to_string(99); // 99 is casted "99" and the value is assigned

→to str_val
```

```
[2]: str_val
```

[2]: "99"

```
[3]: // typeinfo library can be used to know the name of data types
      #include <typeinfo>
 [5]: // typeid operator is defined in typeinfo library
      typeid(str val).name()
 [5]: "NSt3__112basic_stringIcNS_11char_traitsIcEENS_9allocatorIcEEEE"
 [7]: int whole_num = 1234;
      string str_val1 = to_string(whole_num);
 [8]: str_val1
 [8]: "1234"
 [7]: float float_num = 129.99f;
      string str_num1 = to_string(float_num);
 [8]: str_num1
 [8]: "129.990005"
[12]: string str_val2 = to_string('A'); // uses ASCII value
[13]: str_val2
[13]: "65"
```

1.17.2 Converting string values to numeric types

- certain values can be converted into numeric types such as int, float, double, etc.
- <cstdlib> provides some functions for us to convert c-string to numeric data
- more on <cstdlib>: http://www.cplusplus.com/reference/cstdlib
- atoi("value") converts string value to integer
 - converts all leading consecutive digits as integer
- atof("value") converts string value to double
- must include <cstdlib> library to use its functions
 - converts all leading consecutive digits and period as floating point number

```
[28]: #include <cstdlib> //atoi and atof
[22]: // converting string to integers
atoi("120")
[22]: 120
[23]: atoi("43543 alphabets")
```

```
[23]: 43543
 [1]: atoi("text 123")
 [1]: 0
[24]: atof("23.55")
[24]: 23.550000
[25]: atof("132.68 text")
[25]: 132.68000
[27]: atof("text 4546.454")
[27]: 0.0000000
     1.17.3 Converting C++ strings into numeric types
        • http://www.cplusplus.com/reference/string/
        • <string> library provides many functions to convert std::string into numeric types
        • stoi() - converts std:string type to integer
        • stof() - converts std::string type to float
        • stol() - converts std::string type to long int
        • stoul() - converts std::string to unsigned long integer
 [1]: #include <string>
      using namespace std;
 [2]: string int_num = "99";
      string float num = "100.99";
 [3]: // typecast string int and string float to corresponding numeric types
      // do + operation on numeric types
      float result = stoi(int_num)+stof(float_num);
 [4]: result
 [4]: 199.99f
```

1.17.4 Type casting among numeric types

- at times, you may need to convert integers to floating points and vice versa
- use int(value) to convert float to int

- use float(value) to convert int or double to float
- use double(value) to convert int or float to double
- don't need to include any library to use these built-in functions

```
[2]: int(10.99) // convert double to int; discard decimal points or round down
[2]: 10
[6]: int(345.567f) // discard decimal points or round down
[6]: 345
[3]: float(19)
[3]: 19.0000f
[7]: double(3.33f) // convert float to double
[7]: 3.3299999
[5]: double(3)
[5]: 3.0000000

1.17.5 Type casting between char and int
• use char(intValue) to convert ASCII int to char
```

• use int(charValue) to convert char to ASCII int

```
[8]: char(65) // ASCII code to char
```

[8]: 'A'

```
[9]: int('A') // char to ASCII code
```

[9]: 65

1.18 Labs

- 1. Variables Lab
 - write a C++ program that produces the following output on console
 - use the partial solution provided in labs/variables/main.cpp
 - observe and note how the special symbols such as single quote, double quotes and black slashes
 - run the program as it is using the provided make file in the stdio folder
 - $\bullet\,$ complete the rest of the ASCII Art by fixing all the FIXMEs
 - write #FIXED next to each FIXME

1.19 Exercises

- 1. Declare some variables required to store information about a student at a university for an a banner system. Assign some values to those variables.
 - see sample answer here exercises/variables/exercise1
- 2. Declare some variables required to store information about an employee at a university. Assign some values to those variables.
- 3. Declare some variables required to store information about a mechandise in a store for inventory management system. Assign some values to those variables.
- 4. Declare some variables required to store information about a rectangular shape. Calculate area and perimeter of a rectangle. Assign some values to those variables.
- 5. Declare variables required to store information about a circle to calculate its area and perimeter. Assign some values to those variables. Calculate area and perimeter.
- 6. Declare some variables required to store information about a hotel room for booking management system.
- 7. Declare some variables required to store length of sides of a triangle. Calculate area using Herons' formula.
 - Search for Heron's formula, if you're not sure what it is.
- 8. Using pencil and paper or Jupyter Notebook, write your full name in binary.
- e.g., Ram Basnet in Binary is:

1.20 Summary

- this notebook discussed data and C++ fundamental data types
- variables are named memory location that store data values
- C++ variables are static and strongly typed
- looked into C++ operators for various data types
- learned about order of operations, PEMDAS
- learned that constants are used to store values that should not be changed in program
- exercises and sample solutions
